

## **PEDAGOGY BASED ON MODERN APPROACHES CAREER-ORIENTED TRAINING METHODOLOGY**

*Khodjamberdiev M.S.  
assistant professor of Andijan state university*

**Abstract.** This work is devoted to the topic of pedagogy teaching methodology based on modern approaches with an emphasis on the profession, in which the theoretical issues of vocational guidance based on STEAM technology were studied.

**Key words:** Technology, educational technology, educational method, STEAM educational technology, person - oriented education, career orientation.

In the period of globalization of the world community, the development of science, technology and technologies and regular changes in production relations similar to production forces are being observed nowadays. The flow of information enters the social life of our Republic at a rapid speed and covers a wide range. Receiving information at a rapid pace, analyzing, processing, theoretically summarizing, summarizing and delivering it to the student is one of the urgent problems facing the educational system.

The application of pedagogical and educational technologies to the educational process serves to positively solve the above-mentioned current problem. Technology (from the Greek "techne" - skill, art, "logos" - understanding, teaching) is the organization of certain (production, social, economic and other) processes at a high level of skill and art. Educational technology (see "an educational technology") is the organization of the educational (teaching) process at a high level of skill and art. Educational technology refers to the general content of the process of achieving the educational goal, that is, the step-by-step implementation of the previously designed educational process on the basis of an integrated system, the development of a system of certain methods, methods and tools to achieve a specific goal, their effective and efficient use, and the educational process. level management is understood. The central problem of educational technology is to ensure the achievement of educational goals through the development of the learner's personality. Educational method is a method of joint activity of teachers and students aimed at solving the complex tasks of the educational process, and educational methodology is a scientifically based method, rule and system of methods of teaching a specific educational subject.

"...the scientific and technical process leading the way to the civilization of the 21st century will give a job and a career to those who can analyze, synthesize, evaluate their intellectual capabilities, as well as develop their adaptive mental and creative abilities better than others - this is a prophecy written almost 30 ears ago Opinions clearly define the requirements for the training of modern specialists [1].

Changes in the socio-economic life of the society create new requirements for the knowledge, skills and qualifications that a new generation of specialists needs to acquire. This applies, firstly, to the wide spread of technologies that require a lot of scientific knowledge, and secondly, to changes in the organization of work and the results of the teaching process.

As stated in the World Declaration on Higher Education for the 21st Century: "...no country can ensure real and sustainable development without having adequate

higher education and research institutions that create a critical mass of qualified and well-educated people..." [2].

Therefore, the development of creative thinking in the youth of our country, which aims to build a legal, just, democratic state and a free civil society with great progress in the future, raising their desire and desire to create new things to the highest possible level should be considered one of the main activities of the education system in the direction of the intended goal and goodness. It is appropriate for professors and teachers of higher educational institutions to use interactive methods, including modern pedagogical and information technologies, aimed at creativity, research, observation, and development of logical thinking of students [3].

Based on the above opinions, in this article, on the basis of STEAM technology, which is one of the modern educational technologies, taking into account the unity of science, education, and production in higher education, the content of physics is science, technology, engineering art and taking into account the integration of mathematical sciences, on the basis of an active approach - orientation to the profession, that is, the issues of providing comprehensive, systematic, complete knowledge for future occupations were considered.

The problem of interconnection of natural-scientific subjects is one of the active problems of contemporary dialectics. This problem is not new from a historical point of view, because this problem arose during the formation of the theory of didactics as a science.

The works of Great foreign pedagogues Ya.A. Comensky, I.G. Pestolev, F. Distverg and others, Russian educational theorists K.D. Ushinsky, V.F. In the books and articles of Odoevsky, they justified the need to implement interdisciplinary communication during the teaching process, because on the basis of this connection, the effectiveness of the educational process can be increased [6].

Interdependence of subjects with similar contents not only improves the quality of students' knowledge, but also allows them to prepare for practice, develops their multifaceted worldview and helps to form a materialistic worldview [4].

From this point of view, the analysis of the literature on STEAM-educational technology shows that this educational technology, taking into account the integration of sciences, based on the technologist-engineer's thinking, acquired theoretical knowledge, acquired skills, skills and competences spirals from simple to complex with life, practice, and production. on account of the fact that it is meant to be developed towards, students should realize and understand the whole, inseparable, unity of the micro and macro world that surrounds us and is always in motion. helps to understand.

On the basis of STEAM technology, students connect the theoretical knowledge they have acquired from science with mathematics and other specific sciences, engineering, design, technology, create their own projects and understand the essence of the operation of devices, and acquire integrated, systematic, scientific knowledge, skills, competences and opportunities [5,6].

STEAM is a non-traditional way of teaching natural sciences, science theory, technology, engineering, art and mathematics.

Unlike traditional education, STEAM-technology leads to the acquisition of knowledge based on the integration of subjects, not separately.

STEAM - educational technology is aimed at developing students' competencies in scientific and technical fields.

Teaching the basics of science on the basis of STEAM-educational technology forms the basic competencies and worldviews necessary for graduates to solve problems that arise in non-standard conditions, develop engineering skills and creativity at all stages of education, and master the labor skills necessary for independent life. At the same time, the implementation of the STEAM-educational program is of particular note, taking into account the increasing demand for the training of quality and modern personnel of pedagogic scientists from all over the world and the demand for engineers who have mastered new techniques and technologies.

By introducing STEAM (Science - natural sciences, Technology - technologies, Engineering - engineering, Art - art, Mathematics - mathematics) education, the literacy level of students will be increased based on the integration of sciences. The introduction of STEAM, based on international experiences, will change the approach to the education system today and the attitude towards learning and education. By focusing on practical skills, students develop willpower, creativity, flexibility, and learn to cooperate with others. In today's era of development in all fields, the reduction of academic and professional disciplines cannot be realized without the concept of STEAM. At the same time, teaching of physical science enables the formation of scientific and technical literacy, engineering skills and competences of graduates of higher education, as well as the professional use of modern technical systems and technologies, mastering the design and management of technical systems. Physics serves as the main integrative mechanism in the continuous education system, teaches to apply the knowledge acquired within the framework of natural, scientific-technical, technological and humanitarian sciences at the meta-science level and helps to strengthen the practical aspects of higher education. By studying physics based on modern requirements, graduates will develop understanding, application, control, improvement and evaluation, design, research, and management of production technologies. By choosing effective and correct technologies, forming non-standard thinking and acting skills, he can create new products, services and new ways of influencing work. Specialists who are ready to learn independently in uncertain situations, able to choose the right profession necessary for independent life by acquiring various professional skills, work hard, acquire new knowledge, work independently and practice in order to achieve perfection, and adapt to rapidly changing economic, political, and social conditions. educates.

Thus, the analysis of the literature on STEAM-educational technology shows that based on this educational technology, the theoretical knowledge, acquired skills, qualifications and competences acquired from science based on the technological-engineering thinking are developed in a spiral manner from simple to complex with life, practice, and production. It helps students to understand and draw conclusions about the micro and macro world that surrounds us and is always in motion.
